

# CSE 6242 / CX 4242: Data and Visual Analytics | Georgia Tech | Spring 2019

## Homework 3 : Hadoop, Spark, Pig and Azure

Prepared by our 30+ wonderful TAs of [CSE6242A,Q.OAN,001.O3/CX4242A](#) for our 1200+ students

### Submission Instructions and Important Notes:

It is important that you read the following instructions carefully and also those about the deliverables at the end of each question or **you may lose points**.

- ☐ **Always check to make sure you are using the most up-to-date assignment** (version number at bottom right of this document).
- ☐ Submit a single zipped file, called "HW3-{GT username}.zip", containing all the deliverables including source code/scripints, data files, and readme. Example: "HW3-jdoe3.zip" if GT account username is "jdoe3". **Only .zip is allowed** (no other format will be accepted). **Your GT username is the one with letters and numbers.**
- ☐ You may discuss high-level ideas with other students at the "whiteboard" level (e.g., how cross validation works, use hashmap instead of array) and review any relevant materials online. **However, each student must write up and submit his or her own answers.**
- ☐ All incidents of suspected dishonesty, plagiarism, or violations of the [Georgia Tech Honor Code](#) will be subject to the institute's Academic Integrity procedures (e.g., reported to and directly handled by the [Office of Student Integrity \(OSI\)](#)). **Consequences can be severe, e.g., academic probation or dismissal, grade penalties, a 0 grade for assignments concerned, and prohibition from withdrawing from the class.**
- ☐ At the end of this assignment, we have specified a folder structure about how to organize your files in a single zipped file. **5 points will be deducted for not following this strictly.**
- ☐ In your final zip file, **do not include any intermediate files** you may have generated to work on the task, unless your script is absolutely dependent on it to get the final result (which it ideally should not be).
- ☐ We may use auto-grading scripints to grade some of your deliverables, so it is extremely important that you strictly follow our requirements.
- ☐ Wherever you are asked to write down an explanation for the task you perform, **stay within the word limit** or you may lose points.
- ☐ Every homework assignment deliverable and every project deliverable comes with a 48-hour "grace period". **Any deliverable submitted after the grace period will get zero credit. We recommend that you plan to finish by the beginning of the grace period in order to leave yourself time for any unexpected issues which might arise.**
- ☐ **We will not consider late submission of any missing parts** of a homework assignment or project deliverable. To make sure you have submitted everything, download your submitted files to double check. You may re-submit your work before the grace period expires. [Canvas automatically appends a "version number" to files that you re-submit](#). You do not need to worry about these version numbers, and there is no need to delete old submissions. **We will only grade the most recent submission.**

**===== DO THIS NOW: apply for AWS Educate account, and set up alarms =====**

Apply for an **AWS Educate** account **RIGHT AWAY** to get \$100 free AWS credit, and verify that the credit has been properly applied on your account. Creating the account can take days and this assignment's computation can take hours to run, so if you do not do this now, you may not be able to submit your work in time, because you may still be \*waiting\* for jobs to complete.

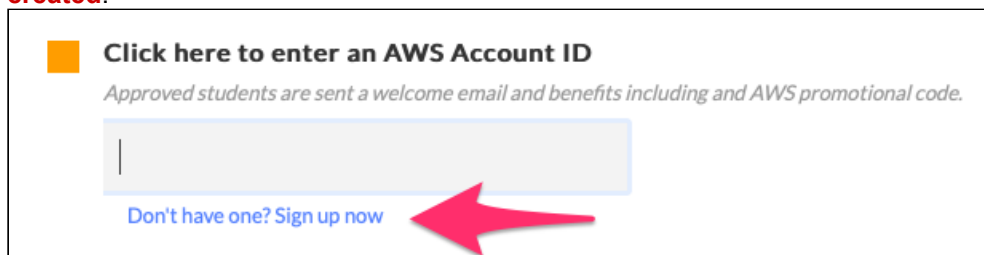

- Go to [AWS Educate page](#)

- Click the **Join AWS Educate Today** button.
- Choose **Student**, and click **Next**
- **Read all the following important points**, then fill out the application form
  - You must use your **@gatech.edu** email address (GT is an AWS member school).
  - For “Grad Month” and “Grad Year” (see below), which stand for graduation month and year, **both of them should be in the future**, since you are still a student and haven’t graduated yet.

**Use future month and year**

- You must stay with the default option--- **you MUST NOT choose the “starter” option** --- or you will NOT receive the full \$100 credit.
- You will need to provide the AWS account ID of your AWS account --- **your AWS account is NOT the same as your AWS Educate account**. If you do not have an AWS account yet (thus, no AWS account ID), sign up for one as indicated in the form (see screenshot below). After your AWS account has been created, **you MUST return to your AWS Educate application to finish signing up, or your AWS Educate will not be created**.

- Your AWS Account ID is at the top of [this screen](#).
- For any emails that you may be receiving from AWS, **please remember to check your “spam” email folders**. Many students reported emails get pushed to those folders automatically.

**EXTREMELY IMPORTANT:** [enable billing alerts AND set up a billing alarm](#) on AWS to notify you when your credits are running low. The AWS Setup Guidelines document in Q3 will show you how to enable alarms.

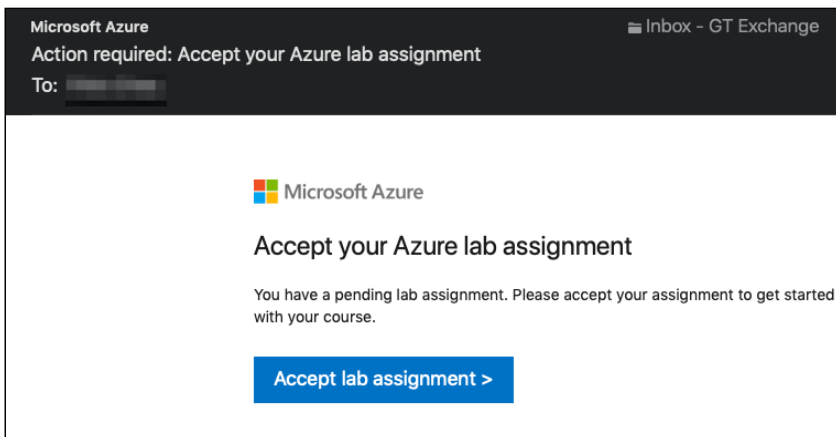

**SHUT DOWN EVERYTHING** when you're done with the instances (don't leave them on over weekends/holidays!), or you may get surprising credit card bills. Highest record from previous classes went above \$2000! **The good news is you can call AWS to explain the situation and they should be able to waive the charges** -- call (phone) AWS customer care **immediately** (not email) so you can resolve the issue quickly (usually within minutes).

=====

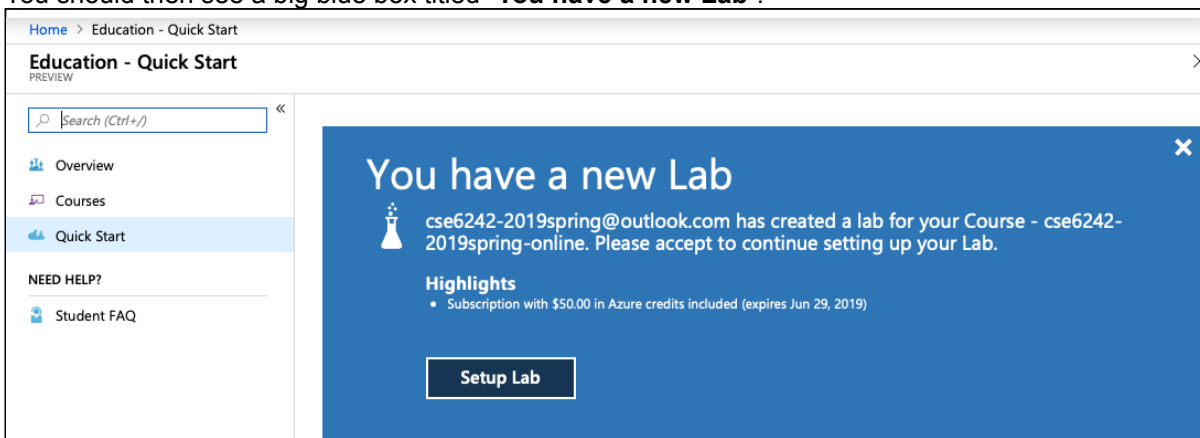

**===== DO THIS NOW: Accept Azure Lab Assignment (\$50 Azure credit) =====**

**VERY IMPORTANT:** Use Firefox or Chrome in incognito/private browsing mode when configuring anything related to Azure (e.g., when using Azure portal), to prevent issues due to browser caches. Safari sometimes loses connections.

By now, you should have received an email sent to your **GTUsername@gatech.edu** email account (your GT username is the one with letters and numbers, e.g., jdoe3). The email is titled **“Action required: Accept your Azure lab assignment”** (see image below). Click **“Accept lab assignment”** to access \$50 Azure credit that we have pre-allocated to you. Log in with your **GTUsername@gatech.edu** email address. You must use this email address, or you may run into issues that we do not know how to solve.

You should then see a big blue box titled “**You have a new Lab**”.

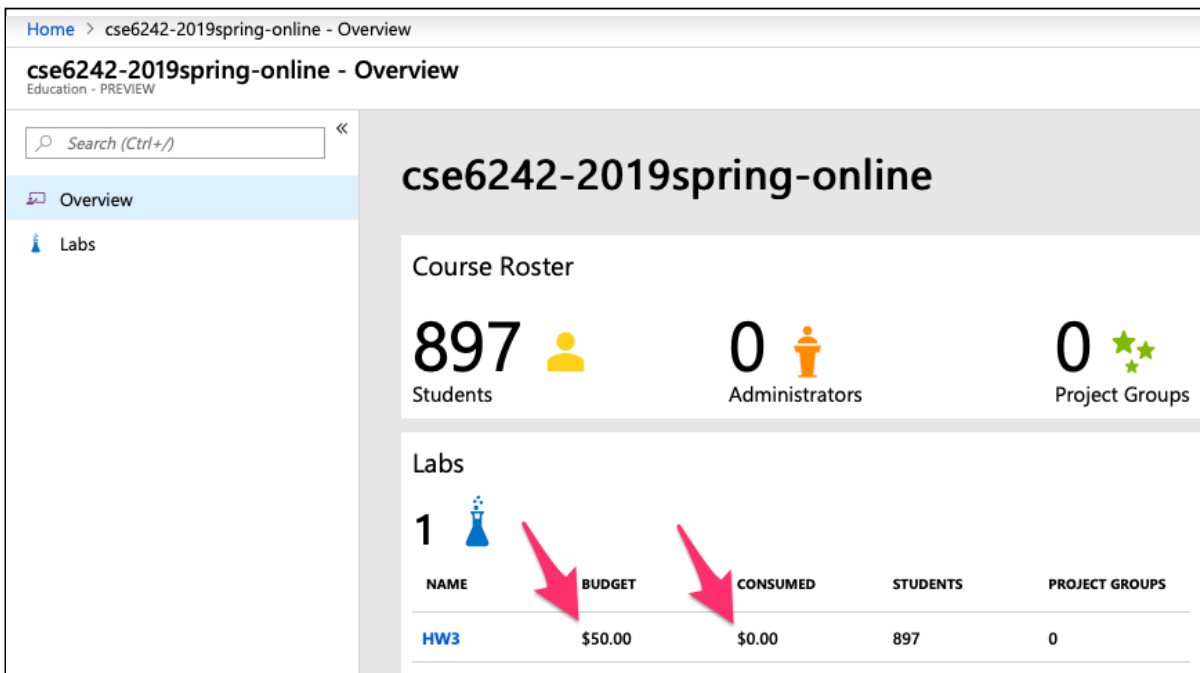

Click “**Setup Lab**” -- you may need to wait for 1-2 minutes (and you may be asked again to login using your GT account). Then, you should see the following gray banner that says “**Lab setup completed successfully**”. Please note that it might take a while until you can use the allocated Azure credit to create a cluster.

Click the “**Go to Lab**” text link to the right of the grey check mark. Then, you should see that \$50 has been applied to your Azure account, as shown in the image below:

If you do not see the “**Go to Lab**” text link, you can use the direct link (for online Sections OAN,O01,O3: [https://portal.azure.com/#blade/Microsoft\\_Azure\\_Education/ClassroomMenuBlade/overview/classroomId/513](https://portal.azure.com/#blade/Microsoft_Azure_Education/ClassroomMenuBlade/overview/classroomId/513), for campus Sections A, Q: [https://portal.azure.com/#blade/Microsoft\\_Azure\\_Education/ClassroomMenuBlade/overview/classroomId/521](https://portal.azure.com/#blade/Microsoft_Azure_Education/ClassroomMenuBlade/overview/classroomId/521)) to confirm that the credit has been applied, as shown in image below. Use the above direct link to check your Azure credit usage as you work on this homework --- keeping in mind that there is **always a lag** between your actual credit consumption and what you see in that panel.

The \$50 Azure credit should be more than enough for this assignment. If you run out of credit, request extra credit by sending us (instructors) a private Piazza post (tag the post with “azurecredit”), with a brief explanation of why you need the credit. **It can take a day or more before you can use the extra credit; if you make last-minute requests, you may not be able to turn in your work in time.**

**VERY IMPORTANT:** Your virtual machine over Azure should only be enabled when you are using Hadoop service. If you are not running any computation over Azure, you should **deallocate your virtual machine** (different from a stopped state) using Azure management portal, to avoid getting charged. Microsoft’s logic here is that you are still occupying some resources over cloud, even if you are not using them for running any computation.

=====

## Grading

You can score a maximum of 120 points in this assignment.

Download the [HW3 Skeleton](#) before you begin.

## Setting up Development Environment for Q1

Installing the Virtual Machine

Download a preconfigured [virtual machine \(VM\) image](#) (~3.0 GB). The virtual image comes with pre-installed Hadoop and Java. You will use them for this HW.

Refer to the [Instructions to setup and configure the VM](#). The account details in the VM are:

username: cse6242

password: cse6242

## Loading Data into HDFS

Now, let us load our dataset into the HDFS (Hadoop Distributed File System), an abstract file system that stores files on clusters. Your Hadoop code will directly access files on HDFS. Paths on the HDFS look similar to those on the UNIX system, but you cannot explore them directly using standard UNIX commands. Instead, you need to use **hadoop fs** commands. For example

```
hadoop fs -ls
```

Download the following two graph files: [graph1.zip<sup>\[1\]</sup>](#) (~5MB when unzipped) and [graph2.zip<sup>\[2\]</sup>](#) (~1.1GB when unzipped) into the VM and unzip them. Also place the Q1 skeleton code in the VM. Use the following commands to setup a directory on the HDFS to store the two graph datasets. Do not change the directory structure below (data/) since we will grade your homework using the scripts that assume the following directory structure. First, navigate to the folder in your skeleton code that contains the **src** directory, **pom.xml**, **run1.sh**, and **run2.sh** files and enter the following commands.

```
hadoop fs -mkdir data
hadoop fs -put <insert path to data file>/graph1.tsv data
hadoop fs -put <insert path to data file>/graph2.tsv data
```

Now both files (graph1.tsv and graph2.tsv) are on HDFS, at **data/graph1.tsv** and **data/graph2.tsv**. To check this, try:

```
hadoop fs -ls data
```

## Setting up Development Environments

We found that compiling and running Hadoop code can be quite complicated. So, we have prepared some skeleton code, compilation scripts, and execution scripts for you that you can use, in the HW3 skeleton folder. You should use this structure to submit your homework.

In the directory of *Q1*, you will find **pom.xml**, **run1.sh**, **run2.sh** and the **src** directory.

- The **src** directory contains a main Java file that you will primarily work on. We have provided some code to help you get started. Feel free to edit it and add your files in the directory, but the main class should be Q1. Your code will be evaluated using the provided **run1.sh** and **run2.sh** file (details below).

- **pom.xml** contains the necessary dependencies and compile configurations for each question. To compile, you can simply call Maven in the corresponding directory (i.e., Q1 where pom.xml exists) by this command:

```
mvn package
```

It will generate a single JAR file in the target directory (i.e., target/q1-1.0.jar). Again, we have provided you some necessary configurations to simplify your work for this homework, but you can edit them as long as our run script works and the code can be compiled using mvn package command.

- **run1.sh**, **run2.sh** are the shell script files that run your code over graph1.tsv (run1.sh) or graph2.tsv (run2.sh) and download the output to a local directory. The output files are named based on its question number and graph number (e.g. q1output1.tsv). You can use these run scripts to test your code. Note that these scripts will be used in grading.

To execute the shell scripts from the command prompt, enter:

```
./run1.sh  
./run2.sh
```

Here's what the above scripts do:

1. Run your JAR on Hadoop specifying the input file on HDFS (the first argument) and output directory on HDFS (the second argument)
2. Merge outputs from output directory and download to local file system.
3. Remove the output directory on HDFS.

## Q1 [15 points] Analyzing a Graph with Hadoop/Java

Imagine that your boss gives you a large dataset which contains an entire email communication network from a popular social network site. The network is organized as a directed graph where each node represents an email address and the edge between two nodes (e.g., Address A and Address B) has a weight stating how many times A wrote to B. You have been tasked with finding which people have received the most emails. Your task is to write a MapReduce program in Java to report, for each node in the graph, the sum of weights among all of the node's inbound edges.

First, go over the [Hadoop word count tutorial](#) to familiarize yourself with Hadoop and some Java basics. You will be able to complete this question with only some knowledge about Java. You should have already loaded two graph files into HDFS and loaded into your HDFS file system in your VM. Each file stores a list of edges as tab-separated-values. Each line represents a single edge consisting of three columns: (source node ID, target node ID, edge weight), each of which is separated by a tab (`\t`). Node IDs and weights are positive integers. Below is a small toy graph, for illustration purposes (on your screen, the text may appear out of alignment).

src	tgt	weight
10	110	3
10	200	1
200	150	30
100	110	10
110	200	15
130	110	67

Your program should not assume the edges to be sorted or ordered in any ways (i.e., your program should work even when the edge ordering is random).

Your code should accept two arguments upon running. The first argument (`args[0]`) will be a path for the input graph file on HDFS (e.g., `data/graph1.tsv`), and the second argument (`args[1]`) will be a path for output directory on HDFS (e.g., `data/q1output1`). The default output mechanism of Hadoop will create multiple files on the output directory such as `part-00000`, `part-00001`, which will be merged and downloaded to a local directory by the supplied run script. Please use the `run1.sh` and `run2.sh` scripts for your convenience.

The format of the output: each line contains a node ID, followed by a tab (`\t`), then by the sum of weights of the node's inbound edges. Lines do not need to be sorted. The following example result is computed based on the toy graph above. Please exclude nodes that do not have incoming edges (e.g., those email addresses which have not received any communication).

For the toy graph above, the output is as follows.

110	80
150	30
200	16

### Deliverables

1. **[5 points] Your Maven project directory including Q1.java.** Please see detailed submission guide at the end of this document. **You should implement your own MapReduce procedure and should not import external graph processing library.**
2. **[5 points] q1output1.tsv:** the output file of processing `graph1.tsv` by `run1.sh`.

3. [5 points] **q1output2.tsv**: the output file of processing graph2.tsv by run2.sh.

## Q2 [25 pts] Analyzing a Large Graph with Spark/Scala on Databricks

**Tutorial:** First, go over this [Spark on Databricks Tutorial](#), to get the basics of creating Spark jobs, loading data, and working with data.

### Goal

Your objectives:

1. Eliminate any duplicate rows.
2. Filter the graph such that only nodes containing an edge weight  $\geq 5$  are preserved.
3. Analyze the graph to find the nodes with the highest weighted-in-degree, weighted-out-degree, and weighted-total-degree using DataFrame operations.
4. Download a new DataFrame to **q2output.csv** containing your analysis (schema provided below).

You will analyze `bitcoinotc.csv`<sup>[3]</sup> using Spark and Scala on the Databricks platform. This graph is a who-trusts-whom network of people who trade using Bitcoin on a platform called Bitcoin OTC. **The dataset has three columns in the following format - Source Node, Target Node, Edge Weight.**

The **weighted-in-degree** of a node is the sum of weights of all the incoming edges to a node, the **weighted-out-degree** is the sum of weights of all the outgoing edges from a node and the **weighted-total-degree** of a node is the sum of its weighted-in-degree and its weighted-out-degree.

You should perform this task using the [DataFrame API](#) in Spark. [Here](#) is a guide that will help you get started on working with data frames in Spark.

A template Scala notebook, `q2-skeleton.dbc` has been included in the HW3-Skeleton that reads in a sample graph file `examplegraph.csv`. In the template, the input data is loaded into a dataframe, inferring the schema using reflection (Refer to the guide above).

**Note:** You **must** use only Scala DataFrame operations for this task. You will lose points if you use SQL queries, Python, or R to manipulate a dataframe.

You may find some of the following DataFrame operations helpful:

`toDF`, `join`, `select`, `groupBy`, `orderBy`, `agg`

Upload the data file `examplegraph.csv` and `q2-skeleton.dbc` to your Databricks workspace before continuing. Follow the [Databricks Setup Guide](#) for further instructions.

Consider the following directed graph example where we show the result of achieving the objectives on `examplegraph.csv`.

**1. Eliminate duplicate edges.** For example, remove the second instance of the edge `src: 1 - tgt: 2` should be removed from the example graph.

src	tgt	weight
1	2	5
1	3	4
.	.	.
.	.	.
5	2	5
<del>1</del>	<del>2</del>	<del>5</del>

**2. Filter graph.** Filter the graph edges to remove any edge whose edge weight is less than 5 (i.e., keep an edge if its weight is  $\geq 5$ ).

src	tgt	weight
1	2	5
<del>1</del>	<del>3</del>	<del>4</del>
1	4	10
2	1	5
2	3	5
2	5	10
3	4	5
<del>4</del>	<del>2</del>	<del>1</del>
4	5	5
4	6	10
5	2	5

**3. Find “important” node.** Find node with highest weighted-in-degree, highest weighted-out-degree, and highest weighted-total-degree. If we analyzed the example graph above, we would see the following:

node	weighted-out-degree	weighted-in-degree	weighted-total-degree
1	15	5	20
2	20	10	30
3	5	5	10
4	15	15	30
5	5	15	20
6	0	10	10

### Notes

If two or more nodes have the same weighted-out-degree, report the one with the **lowest** node id

If two or more nodes have the same weighted-in-degree, report the one with the **lowest** node id

If two or more nodes have the same weighted-total-degree, report the one with the **lowest** node id

Nodes(s) with the highest weighted-in-degree : **4 (Both 4 and 5 have the highest values of weighted in-degree, but 4 is the lower id)**

Node(s) with the highest weighted-out-degree: **2**

Node(s) with highest weighted-total-degree: **2, 4 (Both 2 and 4 have the highest values of weighted total-degree, but 2 is the lower id)**

**4. Record your results.** Create a dataframe to store your results using the following schema:

Three columns, named: 'v', 'd', 'c' where:

**v** : vertex id

**d** : weighted-degree value (an integer value. one row with highest weighted-in-degree, a row with highest weighted-out-degree and a row with highest weighted-total-degree )

**c** : category of weighted-degree, containing one of three string values:

'i' : weighted-in-degree

'o' : weighted-out-degree

't' : weighted-total-degree

Your output can be downloaded as a .csv file or copied to a .csv file, as long as it meets the following requirements:

1. Your output shall contain exactly 4 rows. (1 header row + 3 data rows)
2. The header row shall be of format **v, d, c** and must be the first row.
3. Your output shall contain exactly the column order specified.

4. The order of rows does not matter.

A **correct** output.csv for the input file *examplegraph.csv* would look like:

```
v,d,c
4,15,i
2,20,o
2,30,t
```

Where:

Node 2 has highest weighted-out-degree with a value of 20

Node 4 has highest weighted-in-degree with a value of 15

Node 2 has highest weighted-total-degree with a value of 30

#### Unacceptable formats:

Missing header 4,15,i 2,20,o 2,30,t	Columns are not in correct order c,v,d i,4,15 o,2,20 t,2,30	Wrong category names v,d,c 4,15,i 2,20,p 2,30,t	Header not in first row 4,15,i v,d,c 2,20,o 2,30,t
Missing headers and category suffix 4,15 2,20 2,30	Wrong header format v,c,d 4,15,i 2,20,o 2,30,t	Wrong header names v,d,h 4,15,i 2,20,o 2,30,t	Using delimiter other than comma (e.g., tab) v d c 4 15 i 2 20 o 2 30 t

#### Deliverables

##### 1. [10 pts]

a. **q2.dbc** Your solution as Scala Notebook archive file (.dbc) exported from Databricks. See the Databricks Setup Guide on creating an exportable archive for details.

b. **q2.scala**, Your solution as a Scala source file exported from Databricks. See the Databricks Setup Guide on creating an exportable source file for details.

**Note:** You should export your solution as both a .dbc & a .scala file.

2. [15 pts] **q2output.csv**: The output file of processing *bitcoinotc.csv* from the q2 notebook file. You can download or copy the output of the display() function into a file titled **q2output.csv**.

## Q3 [35 points] Analyzing Large Amount of Data with Pig on AWS

You will try out [Apache Pig](#) for processing n-gram data on Amazon Web Services (AWS). This is a fairly simple task, and in practice you may be able to tackle this using commodity computers (e.g., consumer-grade laptops or desktops). However, we would like you to use this exercise to learn and solve it using distributed computing on Amazon EC2, and gain experience (very helpful for your career), so you will be prepared to tackle problems that are more complex.

The services you will primarily be using are Amazon S3 storage, Amazon Elastic Cloud Computing (EC2) virtual servers in the cloud, and Amazon Elastic MapReduce (EMR) managed Hadoop framework.

For this question, you will only use up a **very small fraction of your \$100 credit**. AWS allows you to use up to 20 instances in total (that means 1 master instance and up to 19 core instances) without filling out a "limit request form". **For this assignment, you should not exceed this quota of 20 instances.** Refer to details about [instance types](#), their specs, and [pricing](#). In the future, for larger jobs, you may want to use [AWS's pricing calculator](#).

## AWS Guidelines

Please read the [AWS Setup Guidelines](#) provided to set up your AWS account.

## Datasets

In this question, you will use subsets of the Google books *n-grams* dataset (full [dataset](#) for reference), on which you will perform some analysis. An '*n*-gram' is a phrase with *n* words; the full *n*-gram dataset lists *n*-grams present in the books on books.google.com along with some statistics.

You will perform your analysis on two custom datasets, extracted from the Google books trigrams (3-grams), that we have prepared for you: a small one `s3://cse6242-2019spring-trigrams-small/*` (~1GB) and a large one `s3://cse6242-2019spring-trigrams-big/*` (~120GB).

**VERY IMPORTANT:** Both the datasets are in the **US East (N. Virginia)** region. Using machines in other regions for computation would incur data transfer charges. Hence, set your region to **US East (N. Virginia)** in the beginning (not Oregon, which is the default). **This is extremely important otherwise your code may not work and you may be charged extra.**

The files in these two S3 buckets are stored in a tab ('\t') separated format. Each line is in the following format:

```
n-gram TAB year TAB occurrences TAB books NEWLINE
```

Some example lines:

```
I am      so 1936      441      90
I am      so 1945      211      25
I am      so 1951      47       12
very cool as      1923      118      10
very cool as      1980      320      100
very cool as      2012      922      302
very cool as      2017      1820     612
```

The above lines tell us that, in 1936, the trigram "I am so" appeared 441 times in 90 different books. In 1945, "I am so" appeared 211 times in 25 different books. And so on.

## Goal

Output the 20 trigrams having the highest **average number of appearances per book** along with their corresponding averages, in **tab-separated format**, sorted in descending order. Only consider entries with at least 400 occurrences and at least 15 books. If multiple trigrams have the same average, **order them alphabetically**. For the example above, the output will be:

```
I am so      4.9
very cool as  3.00
```

Refer to the calculations given below

```
I am so      (441) / (90) = 4.9
very cool as  (922 + 1820) / (302 + 612) = 3.00
```

## Sample Output

To help you evaluate the correctness of your output, we provide you with [the output for the small dataset](#).

**Note:** Please strictly follow the formatting requirements for your output as shown in the small dataset output file. You can use <https://www.diffchecker.com/> to make sure the formatting is correct. Improperly formatting outputs may not receive any points.

## Using PIG (Read these instructions carefully)

There are two ways to debug PIG on AWS (all instructions are in the [AWS Setup Guidelines](#)):

1. **Use the interactive PIG shell** provided by EMR to perform this task from the command line (grunt). Refer to Section 8: Debugging in the AWS Setup Guidelines for a detailed step-by-step procedure. You should use this method if you are using PIG for the first time as it is easier to debug your code. However, as you need to have a persistent ssh connection to your cluster until your task is complete, this is suitable only for the smaller dataset.
2. **Upload a PIG script** with all the commands which computes and direct the output from the command line into a separate file. Once you verify the output on the smaller dataset, use this method for the larger dataset. You don't have to ssh or stay logged into your account. You can start your EMR job, and come back after a few hours when the job is complete!

**Note:** In summary, verify the output for the smaller dataset with Method 1 and submit the results for the bigger dataset using Method 2.

## Sample Commands: Load data in PIG

To load the data from the **s3://cse6242-2019spring-trigrams-small/\*** bucket into a PIG table, you can use the following command:

```
grunt> trigrams = LOAD 's3://cse6242-2019spring-trigrams-small/*' AS (trigram:chararray,  
year:int, occurrences:int, books:int);
```

### Note:

- Refer to other commands such as LOAD, USING PigStorage, FILTER, GROUP, ORDER BY, FOREACH, GENERATE, LIMIT, STORE, etc.
- Copying the above commands directly from the PDF and pasting on console/script file may lead to script failures due to the stray characters and spaces from the PDF file.
- Your script will fail if your output directory already exists. For instance, if you run a job with the output folder as **s3://cse6242oan-<GT account username>/output-small**, the next job which you run with the same output folder will fail. Hence, please use a different folder for the output for every run.
- You might also want to change the input data type for **occurrences** and **books** to handle floating point values.
- While working with the interactive shell (or otherwise), **you should first test on a small subset of the data instead of the whole data (the whole data is over 100 GB)**. Once you believe your PIG commands are working as desired, you can use them on the complete data and wait since it will take some time.

## Deliverables

- **pig-script.txt**: The PIG script for the question (using the **larger** data set).
- **pig-output.txt**: Output (**tab-separated**) (using the **larger** data set).

**Note:** Please strictly follow the guidelines below, otherwise your solution may not be graded.

- Ensure that file names (case sensitive) are correct.
- Ensure file extensions (.txt) are correct.
- The size of each pig-script.txt and pig-output.txt file should not exceed 5 KB.
- Double check that you are submitting the correct set of files --- we only want the script and output from the larger dataset. Also double check that you are writing the right dataset's output to the right file.
- Ensure that unnecessary new lines, brackets, commas etc. aren't in the file.
- Please use tabs (not space) in the output file for separating the 2 columns.

## Q4 [35 points] Analyzing a Large Graph using Hadoop on Microsoft Azure

**VERY IMPORTANT:** Use Firefox or Chrome in incognito/private browsing mode when configuring anything related to Azure (e.g., when using Azure portal), to prevent issues due to browser caches. Safari sometimes loses connections.

## Goal

The goal is to analyze graph using a cloud computing service - Microsoft Azure, and your task is to write a MapReduce program to compute the distribution of a graph's node degree differences (see example below). *Note that this question shares some similarities with Question 1 (e.g., both are analyzing graphs). Question 1 can be completed using your own computer. This question is to be completed using Azure. We recommend that you first complete Question 1. Please carefully read the the following instructions.*

You will use two data files in this questions:

- [small.tsv](#)<sup>[4]</sup> (zipped as ~100MB small.zip; ~400MB when unzipped)
- [large.tsv](#)<sup>[5]</sup> (zipped as 900MB large.zip; ~3GB when unzipped)

Each file stores a list of edges as tab-separated-values. Each line represents a single edge consisting of two columns: (Source, Target), each of which is separated by a tab. Node IDs are positive integers and the rows are already sorted by Source.

Source	Target
1	2
2	1
2	3
3	2
4	2
4	3

Your code should accept two arguments upon running. The first argument (args[0]) will be a path for the input graph file, and the second argument (args[1]) will be a path for output directory. The default output mechanism of Hadoop will create multiple files on the output directory such as part-00000, part-00001, which will have to be merged and downloaded to a local directory (instructions on how to do this are provided below).

The format of the output should be as follows. Each line of your output is of the format

`diff            count`

where

- (1) `diff` is the difference between a node's out-degree and in-degree (i.e., out-degree minus in-degree); and
- (2) `count` is the number of nodes that have the value of `difference` (specified in 1).

The out-degree of a node is the number of edges where that node is the Source. The in-degree of a node is the number of edges where that node is the Target. `diff` and `count` must be separated by a tab (`\t`), and lines do not have to be sorted.

The following result is computed based on the toy graph above.

-1	2
0	1
2	1

The explanation of the above example result:

Output		Explanation
-1	2	There are 2 nodes (node 2 and 3) whose degree difference is -1
0	1	There is 1 node (node 1) whose degree is 0
2	1	There is 1 node (node 4) whose degree difference is 2

**Hint:** One way of doing it is using the mapreduce procedure twice. The first one for finding the difference between out-degree and in-degree for each node, the second for calculating the node count of each degree difference. You will have to make changes in the skeleton code for this.

In the Q4 folder of the hw3-skeleton, you will find the following files we have prepared for you:

- **src** directory contains a main Java file that you will work on. We have provided some code to help you get started. Feel free to edit it and add your files in the directory, but the main class should be called “Q4”.
- **pom.xml** contains necessary dependencies and compile configurations for the question.

To compile, you can run the command in the directory which contains **pom.xml**.

```
mvn clean package
```

This command will generate a single JAR file in the target directory (i.e. target/q4-1.0.jar).

### Creating Clusters in HDInsight using the Azure portal

Azure HDInsight is an Apache Hadoop distribution. This means that it handles large amount of data on demand. The next step is to use Azure’s web-based management tool to create a Linux cluster. Follow the documentation [here](#) to create a new cluster - make sure to use the following settings:

- Select “Quick Create” instead of “Custom”
- “Subscription” drop down menu: there will be only 1 option (“<Lab\_name>+<your\_name>”)
- “Cluster type”: choose “Hadoop 2.7.3 (HDI 3.6)”
- Under the Storage Tab (Step 3 during cluster creation), under the “Select a Storage Account” textbox, select the option “Create New” to create a new storage account. Preferably name your storage account with lowercase letters

At the end of this process, you will have created and provisioned a New HDInsight Cluster and Storage (the provisioning will take some time depending on how many nodes you chose to create). Please record the following important information (we also recommend that you take screenshots) so you can refer to them later:

- Cluster login credentials
- SSH credentials
- Resource group
- Storage account
- Container credentials

**VERY IMPORTANT:** HDInsight cluster billing starts once a cluster is created and stops when the cluster is deleted. To save the credit, you’d better to delete your cluster when it is no longer in use. Please refer [here](#) for how to delete an HDInsight cluster.

### Uploading data files to HDFS-compatible Azure Blob storage

We have listed the main steps from the documentation for uploading data files to your Azure Blob storage here:

1. Follow the documentation [here](#) to install Azure CLI.
2. Open a command prompt, bash, or other shell, and use `az login` command to authenticate to your Azure subscription. When prompted, enter the username and password for your subscription.
3. `az storage account list` command will list the storage accounts for your subscription.
4. `az storage account keys list --account-name <storage-account-name> --resource-group <resource-group-name>` command should return Primary and Secondary keys. Copy the Primary key value because it will be used in the next steps.
5. `az storage container list --account-name <storage-account-name> --account-key <primary-key-value>` command will list your blob containers.
6. `az storage blob upload --account-name <storage-account-name> --account-key <primary-key-value> --file <small or large .tsv> --container-name <container-name> --name <name for the new blob>/<small or large .tsv>` command will upload the source file to your blob storage container.

Using these steps, upload **small.tsv** and **large.tsv** to your blob storage container. The uploading process may take some time. After that, you can find the uploaded files in storage blobs at [Azure](#) (portal.azure.com) by clicking on “Storage accounts” in the left side menu and navigating through your storage account (<Your Storage Account> -> <“Blobs” in the overview tab> -> <Select your Blob container to which you’ve uploaded the dataset> -> <Select the relevant blob folder>). For example, “jonDoeStorage” -> “Blobs” -> “jondoecluster-xxx” -> “jdoeSmallBlob” -> “small.tsv”. After that write your hadoop code locally and convert it to a jar file using the steps mentioned above.

### Uploading your Jar file to HDFS-compatible Azure Blob storage

Azure Blob storage is a general-purpose storage solution that integrates with HDInsight. Your Hadoop code should directly access files on the Azure Blob storage.

Upload the jar file created in the first step to Azure storage using the following command:

```
scp <your-relative-path>/q4-1.0.jar <ssh-username>@<cluster-name>-ssh.azurehdinsight.net:
```

SSH into the HDInsight cluster using the following command:

```
ssh <ssh-username>@<cluster-name>-ssh.azurehdinsight.net
```

**Note:** if you see the warning - REMOTE HOST IDENTIFICATION HAS CHANGED, you may clean `/home/<user>/.ssh/known_hosts`. Please refer to [host identification](#).

Run the `ls` command to make sure that the `q4-1.0.jar` file is present.

To run your code on the `small.tsv` file, run the following command:

```
yarn jar q4-1.0.jar edu.gatech.cse6242.Q4 wasbs://<container-name>@<storage-account-name>.blob.core.windows.net/<name> for  
the new blob>/small.tsv  
wasbs://<container-name>@<storage-account-name>.blob.core.windows.net/smalloutput
```

Command format: `yarn jar jarFile packageName.ClassName dataFileLocation outputDirLocation`

**Note:** if “Exception in thread “main” org.apache.hadoop.mapred.FileAlreadyExistsException...” occurs, you need to delete the output folder from your Blob. You can do this at [portal.azure.com](#).

The output will be located in the `wasbs://<container-name>@<storage-account-name>.blob.core.windows.net/smalloutput`.

If there are multiple output files, merge the files in this directory using the following command:

```
hdfs dfs -cat wasbs://<container-name>@<storage-account-name>.blob.core.windows.net/smalloutput/* > small.out
```

Command format: `hdfs dfs -cat location/* >outputFile`

Then you may exit to your local machine using the command:

```
exit
```

You can download the merged file to the local machine (this can be done either from <https://portal.azure.com/> or by using the `scp` command from the local machine). Here is the `scp` command for downloading this output file to your local machine:

```
scp <ssh-username>@<cluster-name>-ssh.azurehdinsight.net:/home/<ssh-username>/small.out .
```

Using the above command from your local machine will download the `small.out` file into the current directory. Repeat this process for `large.tsv`. Make sure your output file has exactly two columns of values as shown above.

## Deliverables

1. [15pt] **Q4.java & q4-1.0.jar:** Your java code and converted jar file. **You should implement your own map/reduce procedure and should not import external graph processing library.**
2. [10pt] **small.out:** the output file generated after processing `small.tsv`.
3. [10pt] **large.out:** the output file generated after processing `large.tsv`.

## Q5 [10 points] Regression: Automobile price prediction, using Azure ML Studio

**Note:** Create and use a free workspace instance at <https://studio.azureml.net/> instead of your Azure credit for this question.

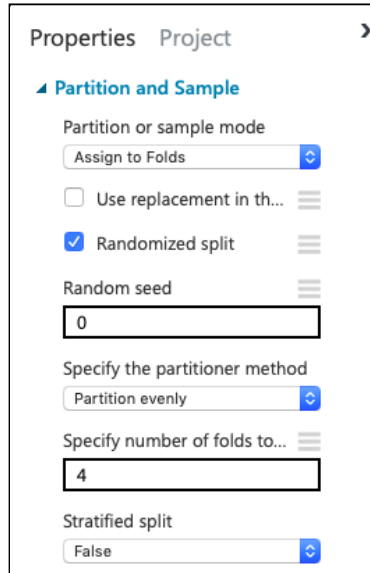

### Goal

This question’s main purpose is to introduce you to Microsoft Azure Machine Learning Studio and familiarize you with its basic functionality and typical machine learning workflow. Go through the “[Automobile price prediction](#)” tutorial and complete the tasks below.

You will modify the given file, **results.csv**, by adding your results for each of the tasks below. We will autograde your

solution, therefore DO NOT change the order of the questions or anything else. Report the exact numbers that you get in your output, DO NOT round the numbers.

1. [3 points] Repeat the experiment mentioned in the tutorial and report the values of the metrics as mentioned in the 'Evaluate Model' section of the tutorial.
2. [3 points] Repeat the same experiment, change the 'Fraction of rows in the first output' value in the split module to 0.9 (originally set to 0.75) and report the corresponding values of the metrics.
3. [4 points] Evaluate the model with the 4-fold cross-validation (CV), select the parameters in the module 'Partition and sample' (Partition and Sample) (see figure below). Report the values of Mean Absolute Error and Relative Squared Error (RSE) for each fold.

The screenshot shows the 'Properties' tab of the 'Partition and Sample' module. The settings are as follows:

- Partition or sample mode: Assign to Folds
- Use replacement in th...: ☐
- Randomized split: ☒
- Random seed: 0
- Specify the partitioner method: Partition evenly
- Specify number of folds to...: 4
- Stratified split: False

Figure: Property Tab of Partition and Sample Module

Specifically, you need to do the following:

- A. Import the entire dataset (Automobile Price Data (Raw))
- B. Clean the missing data by removing rows that have any missing values
- C. Partition and Sample the data.
- D. Create a new model (Linear Regression)
- E. Finally, perform cross validation on the dataset.
- F. Visualize/Report the values.

## Deliverables

1. [10pt] **results.csv**: a csv file containing results for all of the three parts.

**Important: folder structure of the zip file that you submit**

You are submitting a single zip file HW3-GTUsername.zip (e.g., HW3-jdoe3.zip, where "jdoe3" is your GT username), which must unzip to the following directory structure (i.e., a folder "HW3-jdoe3", containing folders "Q1", "Q2", etc.). The files to be included in each question's folder have been clearly specified at the end of each question's problem description above.

```
HW3-GTUsername/  
  Q1/  
    src/main/java/edu/gatech/cse6242/Q1.java  
    pom.xml  
    run1.sh  
    run2.sh  
    q1output1.tsv  
    q1output2.tsv  
    (do not attach target directory)  
  Q2/  
    q2.dbc  
    q2.scala  
    q2output.csv
```

Q3/  
    pig-script.txt  
    pig-output.txt  
Q4/  
    src/main/java/edu/gatech/cse6242/Q4.java  
    pom.xml  
    q4-1.0.jar **(from target directory)**  
    small.out  
    large.out  
**(do not attach target directory)**  
Q5/  
    results.csv

Version 3

- 
- [1] Graph1 is a modified version of data derived from the LiveJournal social network dataset, with around 30K nodes and 320K edges.
  - [2] Graph2 is a modified version of data derived from the LiveJournal social network dataset, with around 300K nodes and 69M edges.
  - [3] Graph derived from the Stanford Large Network Dataset Collection
  - [4] subset of [Pokec social network](#) data
  - [5] subset of [Friendster](#) data
